

Video 7. Cross validation

MODULE 8 Model evaluation

How to estimate MSE_P if sample is used for calibration

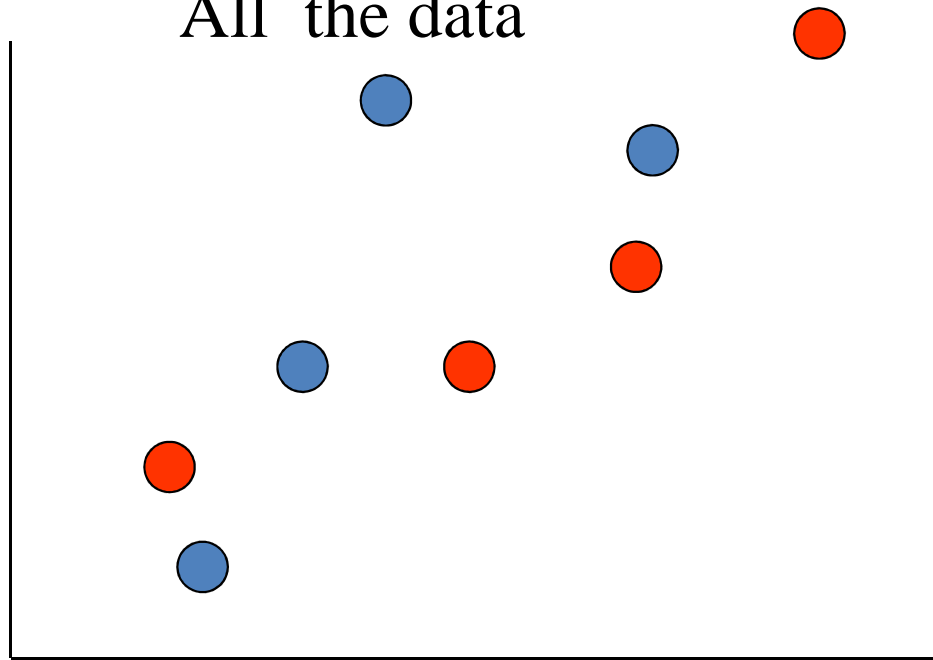

The situation

- We have data from the target population.
- We want to use those data to estimate parameters
- But we also want to estimate MSEP.
- But if we use data for calibration, then MSE is not a good estimator of MSEP.
- What should we do?

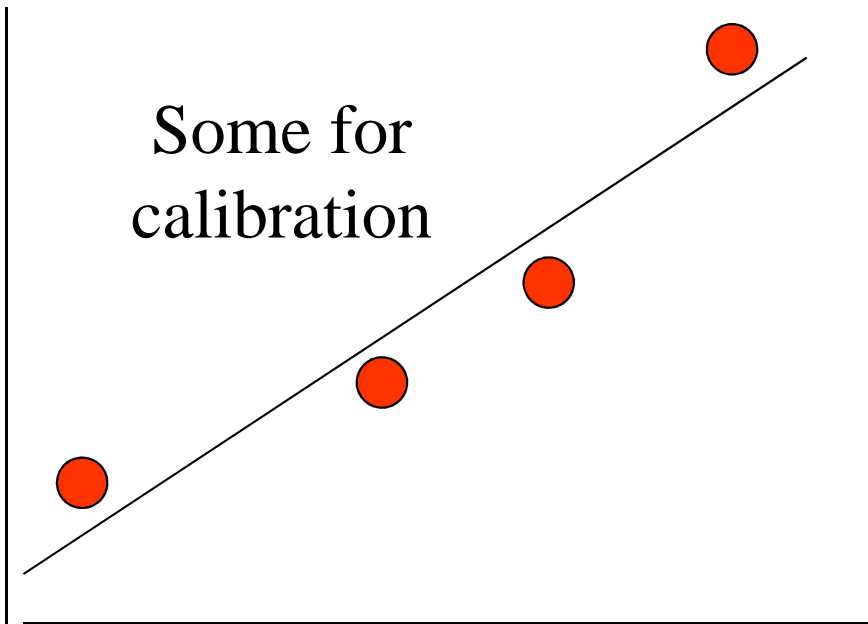

Data splitting

- Divide data into 2 parts, one part for calibration, one part to estimate MSE.
 - The second part isn't used for calibration, so MSE estimates MSE.
 - (Assuming it is random sample from target population)

All the data

Some for
calibration

Some to estimate
MSEP

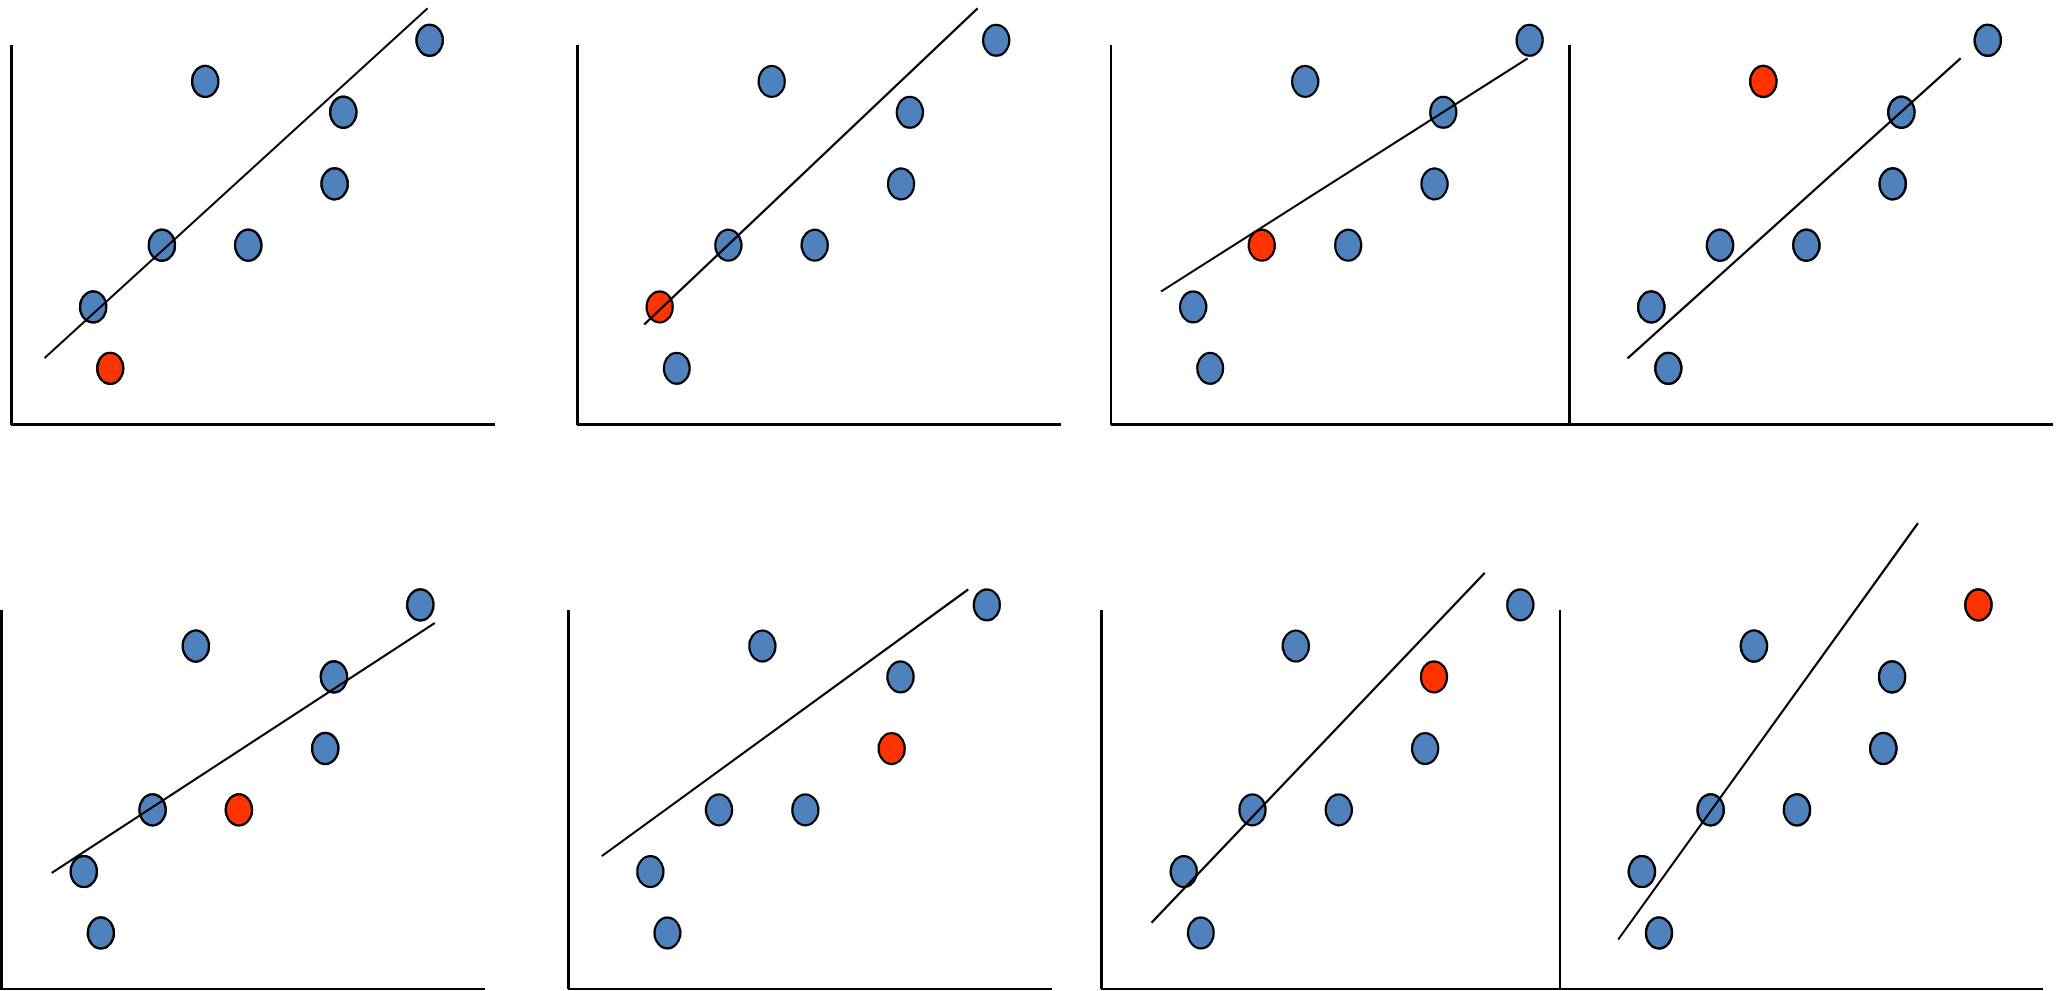

But....

- The division is arbitrary
- Calibration suffers (not all data)
- Estimation of MSEP suffers (not all data)

Cross validation

- A more efficient way to use the data.
- For N data points, do N different divisions of data.
- In each division, calibrate with $N-1$ data points, estimate MSE with one data point.

● used for calibration

● used to calculate prediction error.

Final estimate of MSE_{EP} is average of squared errors.

Calculation

OLS calculation data used for calibration estimate of MSEP

1	Y1 Y2 Y3 YN	$(Y_1 - \hat{Y}_1(\theta_{-1}))^2$
2	Y1 Y2 Y3 YN	$(Y_2 - \hat{Y}_2(\theta_{-2}))^2$
⋮		
N	Y1 Y2 Y3 YN X	$(Y_N - \hat{Y}_N(\theta_{-N}))^2$

$$\hat{MSEP} = 1 / N \sum \left[Y_i - \hat{Y}_i(\theta_{-i}) \right]^2$$

average to get final estimate of MSEP

CV requires independence

between errors of data used for calibration
and errors of data used for calculating error

- If not, again underestimate MSE_P in general
